Search

• for what?
  – a solution
  – the (best possible (approximate?)) solution
• from where?
  – search space (all valid solutions or paths)
• under which conditions?
  – compute time, space, ...
  – constraints, ...

Objective function

• An optimal solution
  – what is the measure that we optimise?
    • Any solution (satisfiability /SAT/ problem)
    – does the task have a solution?
    – is there a solution with objective measure better than X?
  • Minimal/maximal cost solution
  • A winning move in a game
  • A (feasible) solution with smallest nr of constraint violations (e.g. course time scheduling)

Search space size?

• Linear (list, binary search, ...)
• Integer in [i,j]
• Real nr in [x,y]
• A point in high-dimensional space
• An assignment of variables (in SAT)
• A subset of a larger set
• Trees, Graphs
• ...

The Propositional Satisfiability Problem (SAT)

Simple SAT instance (in CNF):

\[(a \lor b) \land (\neg a \lor \neg b)\]

\[\rightarrow\text{satisfiable, two models:}\]

\[a = \text{true}, \ b = \text{false}\]
\[a = \text{false}, \ b = \text{true}\]
Inputs usually in CNF

\[(a + b + c)(a' + b' + c)(a + b' + c')(a' + b + c')\]

Solution search space: lattice for 4 variables (partial connections)

Tic-Tac-Toe

It is straightforward to write a computer program to play Tic-tac-toe perfectly, to enumerate the 765 essentially different positions (the state space complexity), or the 26,830 possible games up to rotations and reflections (the game tree complexity) on this space (2002?)

TSP, nearest neighbour search

TSP, NN suboptimal

An Instance of the Traveling Salesman Problem

Cost of Nearest Neighbor Path, AEDRCA = 550
Issues:

- Time, space...
  - if optimal cannot be found, approximate
- All kinds of secondary characteristics
- Constraints
  - sometimes finding even a point in the valid search space is hard

Types of games

<table>
<thead>
<tr>
<th>Deterministic</th>
<th>Chance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perfect</td>
<td>Imperfect</td>
</tr>
</tbody>
</table>

- chess, checkers
- go, othello
- backgammon
- monopoly
- battleships, blind tictactoe
- bridge, poker, scrabble
- nuclear war

An interesting constrained numerical optimisation test case reported recently is the problem (Bonnier, 1994) of finding a function:

\[ G(y) = \frac{1}{\prod_{i=1}^{n} x_i^2} \]

subject to

\[ \sum_{i=1}^{n} x_i \geq 0.75, \sum_{i=1}^{n} x_i \leq 7 \text{ for } 0 \leq x_i \leq 10, \text{ and } n \leq 10 \text{ for } 1 \leq i \leq n. \]

Function \( G(y) \) is nowhere and its global maximum is unknown, lying somewhere near the origin. The problem has one nonlinear constraint and one linear constraint; the latter one is inactive around the origin and will be forgotten in the following.

\[ G(x) = (\Sigma \cos^2(x_i) - 2 \prod \cos^2(x_i))/\sqrt{\Sigma x_i^2}, \]

where \( 0 \leq x_i \leq 10 \) and

\[ \Sigma x_i \geq 0.75 \]

In numerical analysis, Newton’s method (also known as the Newton-Raphson method), named after Isaac Newton and Joseph Raphson, is a method for finding successively better approximations to the roots (or zeroes) of a real-valued function.

\[ x : f(x) = 0. \]

The Newton-Raphson method in one variable is implemented as follows:

Given a function \( f \) defined over the reals \( x \), and its derivative \( f’ \), we begin with a first guess \( x_0 \) for a root of the function \( f \). Provided the function satisfies all the assumptions made in the derivation of the formula, a better approximation \( x_1 \) is

\[ x_1 = x_0 - \frac{f(x_0)}{f’(x_0)} \]

Geometrically, \( (x_0, 0) \) is the intersection with the x-axis of a line tangent to \( f(x_0) / f’(x_0) \). The process is repeated as

\[ x_{n+1} = x_n - \frac{f(x_n)}{f’(x_n)} \]

until a sufficiently accurate value is reached.
Examples

- Greedy
- A* search
- Monte Carlo, Grid
- Local search algorithms - Hill-climbing, beam, ...
- Simulated annealing search
- Genetic algorithms (GA, GP)
- Differential Evolutions (DE)
- Particle Swarm Optimisation (PSO)
- Ant colony optimisation (ACO)

Greedy

- Always choose the next seemingly best step

Set Cover

- Greedy Approximation Algorithm
- polynomial-time \( \rho(n) \)-approximation algorithm
  - \( \rho(n) \) is a logarithmic function of set size
  - \( n \) – size of the largest set...
  - \( | C(\text{greedy}) | < \ln(n) \ast | C(\text{optimal}) | \)

Set Cover Problem

Instance \((X, F)\):

- finite set \( X \) (e.g. of points)
- family \( F \) of subsets of \( X \)

\[ X = \bigcup_{S \in F} S \]

Problem: Find a minimum-sized subset \( C \subseteq F \)
whose members cover all of \( X \):

\[ X = \bigcup_{S \in C} S \]

NP-Complete
Greedy Set Covering Algorithm

Let $C$ be an optimal cover

$$
\sum_{i=1}^{k} \sum_{c \in C_i} c_i = \sum_{c \in C} c
$$

1. $U \leftarrow X$
2. $C \leftarrow \emptyset$
3. while $U \neq \emptyset$
   a. do select an $S \in \mathcal{F}$ that maximizes $|S \cap U|$.
   b. $C \leftarrow C \cup \{S\}$
   c. $U \leftarrow U \setminus S$
4. return $C$

Proof of approximation

- http://www.cs.dartmouth.edu/~ac/Teach/CS105-Winter05/Notes/wan-ba-notes.pdf
Local Search

Local search algorithms

- In many optimization problems, the path to the goal is irrelevant; the goal state itself is the solution
- State space = set of "complete" configurations
- Find configuration satisfying constraints, e.g., n-queens
- In such cases, we can use local search algorithms
- keep a single "current" state, try to improve it

Example: n-queens

- Put n queens on an n × n board with no two queens on the same row, column, or diagonal
- may get stuck...

Problems

- Cycles
  - Memorize; Tabu search
- How to transfer valleys with bad choices only...

Tree/Graph search

- order defined by picking a node for expansion
- BFS, DFS
- Random, Best First, ...  
  - Best – an evaluation function
**A***

- \( f(n) = g(n) + h(n) \)
- \( g(n) \) – path covered so far in graph
- \( h(n) \) – estimated distance from \( n \) to goal

**Admissible heuristics**

- A heuristic \( h(n) \) is admissible if for every node \( n \), \( h(n) \leq h'(n) \), where \( h'(n) \) is the true cost to reach the goal state from \( n \).
- An admissible heuristic never overestimates the cost to reach the goal, i.e., it is optimistic.
- Example: \( h_{sld}(n) \) (never overestimates the actual road distance) (SLD – shortest linear distance)
- Theorem: If \( h(n) \) is admissible, \( A^* \) using TREE-SEARCH is optimal.

**Optimality of \( A^* \) (proof)**

- Suppose some suboptimal goal \( G_j \) has been generated and is in the fringe. Let \( n \) be an unexpanded node in the fringe such that \( n \) is on a shortest path to an optimal goal \( G \).

  \[
  f(G_j) = g(G_j) \quad \text{since } h(G_j) = 0 \\
  g(G_j) \geq g(G) \quad \text{since } G_j \text{ is suboptimal} \\
  f(G) = g(G) \quad \text{since } h(G) = 0 \\
  g(G) > g(G) \quad \text{from above} \\
  \] 

  Hence \( f(G_j) > f(n) \), and \( A^* \) will never select \( G_j \) for expansion.

**A* path-finder**

The Traveling Salesperson Problem (TSP)

- TSP – optimization variant:
  - For a given weighted graph \( G = (V,E,w) \), find a Hamiltonian cycle in \( G \) with minimal weight,
  - i.e., find the shortest round-trip visiting each vertex exactly once.
- TSP – decision variant:
  - For a given weighted graph \( G = (V,E,w) \), decide whether a Hamiltonian cycle with minimal weight \( \leq b \) exists in \( G \).

The Traveling Salesperson Problem (TSP)

- TSP – optimization variant:
  - For a given weighted graph \( G = (V,E,w) \), find a Hamiltonian cycle in \( G \) with minimal weight,
  - i.e., find the shortest round-trip visiting each vertex exactly once.
- TSP – decision variant:
  - For a given weighted graph \( G = (V,E,w) \), decide whether a Hamiltonian cycle with minimal weight \( \leq b \) exists in \( G \).

Search Methods

- Types of search methods:
  - systematic \( \leftrightarrow \) local search
  - deterministic \( \leftrightarrow \) stochastic
  - sequential \( \leftrightarrow \) parallel
Local Search (LS) Algorithms

- search space $S$
  (SAT: set of all complete truth assignments to propositional variables)
- solution set $S' \subseteq S$
  (SAT: models of given formula)
- neighborhood relation $N \subseteq S \times S$
  (SAT: neighboring variable assignments differ in the truth value of exactly one variable)
- evaluation function $g : S \rightarrow \mathbb{R}^+$
  (SAT: number of clauses unsatisfied under given assignment)

Local Search:

- start from initial position
- iteratively move from current position to neighboring position
- use evaluation function for guidance

Two main classes:
- local search on partial solutions
- local search on complete solutions

Local search for partial solutions

- Order the variables in some order.
- Span a tree such that at each level a given value is assigned a value.
- Perform a depth-first search.
- But, use heuristics to guide the search. Choose the best child according to some heuristics.
  (DFS with node ordering)

DFS

- Once a solution has been found (with the first dive into the tree) we can continue search the tree with DFS and backtracking.

Construction Heuristics for partial solutions

- search space: space of partial solutions
- search steps: extend partial solutions with assignment for the next element
- solution elements are often ranked according to a greedy evaluation function
Nearest Neighbor heuristic for the TSP:
- at any city, choose the closest yet unvisited city
  - choose an arbitrary initial city \( \pi(1) \)
  - at the \( i \)th step choose city \( \pi(i+1) \) to be the city \( j \) that minimises \( d(\pi(i), j); j \neq \pi(k), 1 \leq k \leq i \)
- running time: \( O(n^2) \)
- worst case performance:
  \[ NN(x)/OPT(x) \leq 0.5(\lfloor \log_2 n \rfloor + 1) \]
- other construction heuristics for TSP are available

Nearest neighbor tour through 532 US cities

My current best is 27486.19940966355 (nn gives 27766.484757657887)
All the best, Polina

My best is 24839.308924381 (Jaak S)

My new best is 23474 (Oleg)

23297.72476804589
Probably some local minimum near Jaak Sarv's solution
local search on complete solutions

Iterative Improvement (Greedy Search):

- initialize search at some point of search space
- in each step, move from the current search position to a neighboring position with better evaluation function value

Iterative Improvement for SAT

- initialization: randomly chosen, complete truth assignment
- neighborhood: variable assignments are neighbors iff they differ in truth value of one variable
- neighborhood size: $O(n)$ where $n$ = number of variables
- evaluation function: number of clauses unsatisfied under given assignment

Hill climbing

- Choose the neighbor with the largest improvement as the next state

```
function Hill-Climbing(problem) returns a solution state
    current ← Make-Node(Initial-State[problem])
    loop do
        next ← a highest-valued successor of current
        if Value[next] < Value[current] then return current
        current ← next
    end
```

while $f$-value($state$) > $f$-value(next-best($state$))

```latex
\textbf{states}
```

```latex
\textbf{f-value}\quad \textbf{f-value = evaluation($state$)}
```

```latex
\textbf{states}
```

```latex
while f-value(state) > f-value(next-best(state))
```
## Problems with local search

Typical problems with local search (with hill climbing in particular)

- getting stuck in local optima
- being misguided by evaluation/objective function

## Stochastic Local Search

- randomize initialization step
- randomize search steps such that suboptimal/worsening steps are allowed
- improved performance & robustness
- typically, degree of randomization controlled by noise parameter

## Stochastic Local Search

**Pros:**

- for many combinatorial problems more efficient than systematic search
- easy to implement
- easy to parallelize

**Cons:**

- often incomplete (no guarantees for finding existing solutions)
- highly stochastic behavior
- often difficult to analyze theoretically/empirically

## Simple SLS methods

- **Random Search (Blind Guessing):**
  - in each step, randomly select one element of the search space.
- **(Uninformed) RandomWalk:**
  - in each step, randomly select one of the neighbouring positions of the search space and move there.

## Random restart hill climbing

**Randomized Iterative Improvement:**

- initialize search at some point of search space search steps:
- with probability \( p \), move from current search position to a randomly selected neighboring position
- otherwise, move from current search position to neighboring position with better evaluation function value.
- Has many variations of how to choose the randomly neighbor, and how many of them
- Example: Take 100 steps in one direction (Army mistake correction) – to escape from local optima.
Search space

• Problem: depending on initial state, can get stuck in local maxima

General iterative Algorithms

– general and “easy” to implement
– approximation algorithms
– must be told when to stop
– hill-climbing
– convergence

General iterative search

• Algorithm
  – Initialize parameters and data structures
  – construct initial solution(s)
  – Repeat
    • Repeat
      – Generate new solution(s)
      – Select solution(s)
    • Until time to adapt parameters
    • Update parameters
    – Until time to stop
  • End

Iterative search

• Most popular algorithms of this class
  – Simulated Annealing
    • Probabilistic algorithm inspired by the annealing of metals
  – Tabu Search
    • Meta-heuristic which is a generalization of local search
  – Genetic Algorithms
    • Probabilistic algorithm inspired by evolutionary mechanisms

Hill-climbing search

• Problem: depending on initial state, can get stuck in local maxima

Simulated annealing

Combinatorial search technique inspired by the physical process of annealing (Kirkpatrick et al. 1983, Cerny 1985)

Outline
• Select a neighbor at random.
• If better than current state go there.
• Otherwise, go there with some probability.
• Probability goes down with time (similar to temperature cooling)
Simulated annealing

Simulated annealing (SA) is a generic heuristic for the global optimization of combinatorial or continuous spaces of solutions. The heuristic is usually compared to the heat annealing process in metallurgy, where a material is heated and then slowly cooled to decrease its internal energy and obtain a minimized state.

Simulated annealing is a probabilistic metaheuristic for the global optimization of given functions. SA was first introduced by Scott Kirkpatrick, C. Daniel Gelatt Jr., and Mario P. Vecchi in 1983. It is an acceptance criterion for the local optimization algorithm called Metropolis-Hastings.[1][2]

**Pseudo code**

```plaintext
function Simulated-Annealing(problem, schedule) returns solution state
    current ← Make-Node(Initial-State[problem])
    for t ← 1 to infinity
        T ← schedule[t]  // T goes downwards.
        if T = 0 then return current
        next ← Random-Successor(current)
        ΔE ← f-Value[next] - f-Value[current]
        if ΔE > 0 then current ← next
        else current ← next with probability e^(ΔE/T)
end
```

**Acceptance criterion**

- Metropolis acceptance criterion
  - better solutions are always accepted
  - worse solutions are accepted with probability

\[
e^{-\frac{\Delta E}{T}}
\]

**Annealing**

- parameter \( T \), called temperature, is slowly decreased

**Generic choices for annealing schedule**

- initial temperature \( T_0 \)
  (example: based on statistics of evaluation function)
- cooling schedule — how to change temperature over time
  (example: geometric cooling, \( T_{t+1} = \alpha \cdot T_t, \alpha = 0, 1, \ldots \))
- number of iterations at each temperature
  (example: multiple of the neighbourhood size)
- stopping criterion
  (example: no improved solution found for a number of temperature values)
Example application to the TSP [Johnson & McGeoch 1997]

Baseline implementation:
- start with random initial solution
- use 2-exchange neighborhood
- simple annealing schedule;
  → relatively poor performance
Improvements:
- look-up table for acceptance probabilities
- neighborhood pruning
- low-temperature starts

Diameter of the search graph

- Simulated annealing may be modeled as a random walk on a search graph, whose vertices are all possible states, and whose edges are the candidate moves. An essential requirement for the neighbour() function is that it must provide a sufficiently short path on this graph from the initial state to any state which may be the global optimum. (In other words, the diameter of the search graph must be small.) In the traveling salesman example above, for instance, the search space for \( n = 20 \) cities has
\[
\text{nl = 2432902008176640000 (2.4\text{ quintillion}) states; yet the neighbour generator function that swaps two consecutive cities can get from any state (tour) to any other state in maximum } n(n - 1) / 2 = 190 \text{ steps.}
\]

Summary-Simulated Annealing

Simulated Annealing . . .
- is historically important
- is easy to implement
- has interesting theoretical properties (convergence), but these are of very limited practical relevance
- achieves good performance often at the cost of substantial run-times

Examples for combinatorial problems:
- finding shortest/cheapest round trips (TSP)
- finding models of propositional formulae (SAT)
- planning, scheduling, time-tableting
- resource allocation
- protein structure prediction
- genome sequence assembly

SAT

SAT Problem – decision variant:
For a given propositional formula \( \Phi \),
\[ \text{decide whether } \Phi \text{ has at least one model.} \]

SAT Problem – search variant:
For a given propositional formula \( \Phi \), if \( \Phi \) is satisfiable, find a model, otherwise declare \( \Phi \) unsatisfiable.
The Propositional Satisfiability Problem (SAT)

Simple SAT instance (in CNF):

\[(a \lor b) \land (\neg a \lor \neg b)\]

\(\sim\) satisfiable, two models:

\[a = \text{true}, b = \text{false}\]

\[a = \text{false}, b = \text{true}\]

Tabu Search

- Combinatorial search technique which heavily relies on the use of an explicit memory of the search process [Glover 1989, 1990] to guide search process
- memory typically contains only specific attributes of previously seen solutions
- simple tabu search strategies exploit only short term memory
- more complex tabu search strategies exploit long term memory

Tabu search – exploiting short term memory

- in each step, move to best neighboring solution although it may be worse than current one
- to avoid cycles, tabu search tries to avoid revisiting previously seen solutions by basing the memory on attributes of recently seen solutions
- tabu list stores attributes of the \(tl\) most recently visited
- solutions; parameter \(tl\) is called tabu list length or tabu tenure
- solutions which contain tabu attributes are forbidden

Example: Tabu Search for SAT / MAX-SAT

- **Neighborhood**: assignments which differ in exactly one variable instantiation
- **Tabu attributes**: variables
- **Tabu criterion**: flipping a variable is forbidden for a given number of iterations
- **Aspiration criterion**: if flipping a tabu variable leads to a better solution, the variable’s tabu status is overridden

[Hansen & Jaumard 1990; Selman & Kautz 1994]

Bart Selman, Cornell
www-verimag.imag.fr/~maler/TCC/selman-tcc.ppt

Ideas from physics, statistics, combinatorics, algorithmics ...

Fundamental challenge: Combinatorial Search Spaces

- *Significant progress in the last decade.*
- How much?

  - for propositional reasoning:
    - We went from 100 variables, 200 clauses (early 90’s)
    - to 1,000,000 vars. and 5,000,000 constraints in
    - 10 years. Search space: from \(10^{30}\) to \(10^{300,000}\).
  - Applications: Hardware and Software Verification,
    - Test pattern generation, Planning, Protocol Design,
    - Routers, Timetabling, E-Commerce [combinatorial
    - auctions], etc.
• How can one deal with such large combinatorial spaces and still do a decent job?
• I’ll discuss recent formal insights into combinatorial search spaces and their practical implications that make searching such ultra-large spaces possible.
• Brings together ideas from physics of disordered systems (spin glasses), combinatorics of random structures, and algorithms.
  • But first, what is BIG?

What is BIG?
Consider a real-world Boolean Satisfiability (SAT) problem.

The instances loc-iter-5-cofl, IBM 1997:

\[ \text{g cofl} \]
-1 7 0
-1 8 0
-1 10 0
-1 12 0
-1 14 0
etc.

\[ x_1 \text{ or } x_2 \text{ or } x_3 \text{ etc. our Boolean variables (let to True or False)} \]

Set \( x_1 \) to False ??

10 pages later:

185 - 9 0
185 - 1 0
177 169 168 153 145 137 130 121 113 105 97
99 81 73 65 57 49 41
33 32 17 9 1 105 0
189 - 97 0
189 - 105 0

...\n
I.e., \((\text{not } x_1) \text{ or } x_7\) \((\text{not } x_1) \text{ or } x_6\) etc.

 clauses / constraints are getting more interesting...

Note \( x_1 \) ...

4000 pages later:

Finally, 15,000 pages later:

Combinatorial search space of truth assignments: \( \Phi^{390} = 1.9996407 \times 10^{390} \)

Current SAT solvers solve this instance in approx. 1 minute!

Genetic Algorithms: A Tutorial

“Genetic Algorithms are good at taking large, potentially huge search spaces and navigating them, looking for optimal combinations of things, solutions you might not otherwise find in a lifetime.”

– Salvatore Mangano

Computer Design, May 1995

The Genetic Algorithm

• Directed search algorithms based on the mechanics of biological evolution
  • Developed by John Holland, University of Michigan (1970’s)
    ♦ To understand the adaptive processes of natural systems
    ♦ To design artificial systems software that retains the robustness of natural systems

The Genetic Algorithm (cont.)

• Provide efficient, effective techniques for optimization and machine learning applications
  • Widely-used today in business, scientific and engineering circles

Components of a GA

A problem to solve, and ...
  • Encoding technique (gene, chromosome)
  • Initialization procedure (creation)
  • Evaluation function (environment)
  • Selection of parents (reproduction)
  • Genetic operators (mutation, recombination)
  • Parameter settings (practice and art)
### Simple Genetic Algorithm

```java
{ initialize population; evaluate population; while TerminationCriteriaNotSatisfied { select parents for reproduction; perform recombination and mutation; evaluate population; } }
```

### The GA Cycle of Reproduction

![Diagram showing the GA cycle of reproduction]

### Genetic algorithms

- How to generate the next generation.
- **1) Selection**: we select a number of states from the current generation. (we can use the fitness function in any reasonable way)
- **2) crossover**: select 2 states and reproduce a child.
- **3) mutation**: change some of the genues.

### Example

![Stochastic local beam search example]

### 8-queen example

- GAs require states encoded as strings (CPs use programs)
- Crossover helps if substrings are meaningful components

### Summary: Genetic Algorithms

**Genetic Algorithms**

- use populations, which leads to increased search space exploration
- allow for a large number of different implementation choices
- typically reach best performance when using operators that are based on problem characteristics
- achieve good performance on a wide range of problems
### Classes of Search Techniques

- **Search techniques**
  - Evolutionary techniques
  - Population methods
  - Genetic methods

#### Evolutionary techniques
- **Evolutionary strategies**
  - Centralized
  - Distributed
  - Parallel
  - Steady-state
  - Generational
  - Sequential

#### Genetic algorithms
- **Evolutionary algorithms**
- **Simulated annealing**

#### Guided random search techniques
- **Dynamic programming**
- **Enumerative techniques**

---

### Example application: evolving checkers players (Fogel’02)

- **Neural nets for evaluating future values of moves are evolved**
- **NNs have fixed structure with 5046 weights, these are evolved + one weight for “kings”**
- **Representation:**
  - vector of 5046 real numbers for object variables (weights)
  - vector of 5046 real numbers for $\sigma$’s
- **Mutation:**
  - Gaussian, lognormal scheme with $\sigma$-first
  - Plus special mechanism for the kings’ weight
- **Population size 15**

---

### Example application: evolving checkers players (Fogel’02)

- **Tournament size $q = 5$**
- **Programs (with NN inside) play against other programs, no human trainer or hard-wired intelligence**
- **After 840 generation (6 months!) best strategy was tested against humans via Internet**
- **Program earned “expert class” ranking outperforming 99.61% of all rated players**

---

### The GA Cycle of Reproduction

- **Population**
  - Chromosomes could be:
    - Bit strings
      - (0101 ... 1100)
    - Real numbers
      - (43.2 -33.1 ... 0.0 89.2)
    - Permutations of elements
      - (E11 E3 E7 ... E1 E15)
    - Lists of rules
      - (R1 R2 R3 ... R22 R23)
    - Program elements
      - (genetic programming)
    - any data structure ...

- **Reproduction**
  - Parents are selected at random with selection chances biased in relation to chromosome evaluations.
Chromosome Modification

Modifications are stochastically triggered
Operator types are:
- Mutation
- Crossover (recombination)

Mutation: Local Modification
Before: (1 0 1 0 1 1 0 1 0 1 1 0)
After: (0 1 1 0 1 1 0 1 1 0)

Before: (1.38 -69.4 326.44 0.1)
After: (1.38 -67.5 326.44 0.1)

Causes movement in the search space (local or global)
Restores lost information to the population

Crossover: Recombination

Crossover is a critical feature of genetic algorithms:
- It greatly accelerates search early in evolution of a population
- It leads to effective combination of schemata (subsolutions on different chromosomes)

Evaluation

The evaluator decodes a chromosome and assigns it a fitness measure
The evaluator is the only link between a classical GA and the problem it is solving

Deletion

Generational GA:
- entire populations replaced with each iteration
Steady-state GA:
- a few members replaced each generation

An Abstract Example
A Simple Example

"The Gene is by far the most sophisticated program around."
- Bill Gates, Business Week, June 27, 1994

The Traveling Salesman Problem:
Find a tour of a given set of cities so that
- each city is visited only once
- the total distance traveled is minimized

Representation

Representation is an ordered list of city numbers known as an order-based GA.

1) London 3) Dunedin 5) Beijing 7) Tokyo
2) Venice 4) Singapore 6) Phoenix 8) Victoria

CityList1: (3 5 7 2 1 6 4 8)
CityList2: (2 5 7 6 8 1 3 4)

Crossover

Crossover combines inversion and recombination:

Parent1: (3 5 7 2 1 6 4 8)
Parent2: (2 5 7 6 8 1 3 4)
Child: (5 8 7 2 1 6 3 4)

This operator is called the Order1 crossover.

Mutation

Mutation involves reordering of the list:

Before: (5 8 7 2 1 6 3 4)
After: (5 8 6 2 1 7 3 4)

TSP Example: 30 Cities
Solution \(i\) (Distance = 941)

Solution \(j\) (Distance = 800)

Solution \(k\) (Distance = 652)

Best Solution (Distance = 420)

Overview of Performance

Considering the GA Technology

"Almost eight years ago ... people at Microsoft wrote a program [that] uses some genetic things for finding short code sequences. Windows 2.0 and 3.2, NT, and almost all Microsoft applications products have shipped with pieces of code created by that system."

-Nathan Myhrvold, Microsoft Advanced Technology Group, Wired, September 1995
Issues for GA Practitioners

- Choosing basic implementation issues:
  - representation
  - population size, mutation rate, ...
  - selection, deletion policies
  - crossover, mutation operators
- Termination Criteria
- Performance, scalability
- Solution is only as good as the evaluation function (often hardest part)

Benefits of Genetic Algorithms

- Concept is easy to understand
- Modular, separate from application
- Supports multi-objective optimization
- Good for "noisy" environments
- Always an answer; answer gets better with time
- Inherently parallel; easily distributed

Benefits of Genetic Algorithms (cont.)

- Many ways to speed up and improve a GA-based application as knowledge about problem domain is gained
- Easy to exploit previous or alternate solutions
- Flexible building blocks for hybrid applications
- Substantial history and range of use

When to Use a GA

- Alternate solutions are too slow or overly complicated
- Need an exploratory tool to examine new approaches
- Problem is similar to one that has already been successfully solved by using a GA
- Want to hybridize with an existing solution
- Benefits of the GA technology meet key problem requirements

Some GA Application Types

<table>

Review

4 main types of Evolutionary Algorithms

- Genetic Algorithm - John Holland
- Genetic Programming - John Koza
- Evolutionary Programming - Lawerence Fogel
- Evolutionary Strategies - Ingo Rechenberg
Genetic Algorithms

- Most widely used
- Robust
- uses 2 separate spaces
  - search space - coded solution (genotype)
  - solution space - actual solutions (phenotypes)
- Genotypes must be mapped to phenotypes before the quality or fitness of each solution can be evaluated

Genetic Programming

- Specialized form of GA
- Manipulates a very specific type of solution using modified genetic operators
- Original application was to design computer program
- Now applied in alternative areas eg. Analog Circuits
- Does not make distinction between search and solution space.
- Solution represented in very specific hierarchical manner

Evolutionary Strategies

- Like GP no distinction between search and solution space
- Individuals are represented as real-valued vectors.
- Simple ES
  - one parent and one child
  - Child solution generated by randomly mutating the problem parameters of the parent.
- Susceptible to stagnation at local optima

Evolutionary Strategies (cont’d)

- Slow to converge to optimal solution
- More advanced ES
  - have pools of parents and children
- Unlike GA and GP, ES
  - Separates parent individuals from child individuals
  - Selects its parent solutions deterministically

Evolutionary Programming

- Resembles ES, developed independently
- Early versions of EP applied to the evolution of transition table of finite state machines
- One population of solutions, reproduction is by mutation only
- Like ES operates on the decision variable of the problem directly (ie Genotype = Phenotype)
- Tournament selection of parents
  - better fitness more likely a parent
  - children generated until population doubled in size
  - everyone evaluated and the half of population with lowest fitness deleted.

General Idea of Evolutionary Algorithms
Genetic Programming

- Evolves more complex structures - programs, Lisp code, neural networks
- Start with random programs of functions and terminals (data structures)
- Execute programs and give each a fitness measure
- Use crossover to create new programs, no mutation
- Keep best programs
- For example, place Lisp code in a tree structure, functions at internal nodes, terminals at leaves, and do crossover at sub-trees - always legal in Lisp

### Summary

Evolutionary design

- Karl Sims Evolved Virtual Creatures (1994)
  - [http://www.youtube.com/watch?v=F0OHycyp5J8](http://www.youtube.com/watch?v=F0OHycyp5J8)
  - course work - 2005
- [http://vimeo.com/7074089](http://vimeo.com/7074089)
Figure 9.1.7. Extract from an evolutionary tree. The tree has become too large to display clearly, so the artist has restricted the display to include only fragments between one level above and one level below the current frame. Certain frames are not displayed.

Figure 9.1.8. The fractal layout is a continuous version much as they would be in an animation such as in the film "Fractured."
Conclusions

Question: ‘If GAs are so smart, why ain’t they rich?’

Answer: ‘Genetic algorithms are rich - rich in application across a large and growing number of disciplines.’

- David E. Goldberg, Genetic Algorithms in Search, Optimization and Machine Learning

Games:
- Spore (2007)

Ant Colony Optimization (ACO)

1991, M. Dorigo proposed the Ant System in his doctoral thesis

Strong or weak pheromone
TSP

• It can work on dynamic systems, adopting to changes in the environment

Differential Evolution

• Real-valued chromosomes
• \( X = (x_1, x_2, x_3, \ldots, x_n) \)

Evolutionary Approaches

Implementing Differential Evolution
1. randomly initialize population, \( x_p, p = 1 \ldots P \)
2. REPEAT
   a) for each member \( p \), create 1 offspring \( \tilde{x}_p \)
      \( \tilde{x}_p(i) := x_p(i) + F \cdot (x_q(i) - x_r(i)) \) with prob. \( \pi \)
      \( x_p(i) \) with prob. \( 1-\pi \)
   b) decide over replacement (“tournament”):
      if \( f(x_p) < f(\tilde{x}_p) \) then
      \( x_p := \tilde{x}_p \)
UNTIL halting criterion met

Evolutionary Approaches

Implementing Differential Evolution (cont’d)
• continuous search space
• calibrating
  • population size
  • scaling parameter
  • cross-over probability, \( \pi \)
• extensions
  • jitter (add noise to difference vector and \( / or f \))
  • include “elitist” (best solution so far)
  • mapping functions for constraints or search space
Robust Regression (Differential Evolution)

Fitting a regression line using minimum median error as a measure.

\[ aX + bY + c = 0 \]

Find \( a \) and \( c \)

Differential Evolution

Fit any polynomial, use mean or median, add MDL based identification of the degree of polynomial.

\[ A_n X^n + A_{n-1} X^{n-1} + \ldots + A_1 X + A_0 \]

Another Population Based Approach

“Particle Swarm Optimization”

- particles move through solution space
- components of direction ("velocity" \( v \))
  - current direction ("inertia")
  - are drawn to "good" solutions
    (personal best \( x_i \) & overall best \( x^* \) so far)
  \[
  v := v + c_1 \cdot \Delta x_i + c_2 \cdot \Delta x_{best} \\
  x := x + v \\
  \Delta x_i := U(0,1)
  \]

Implementing PSO

1. randomly initialize population, \( x_0 \) and \( v_0 \)
2. REPEAT
   a) for each member \( p_i \), create 1 offspring \( o \)
      \[
      v := x + c_1 \cdot \Delta x_i + c_2 \cdot \Delta x_{best} \\
      o := x + v \\
      \Delta x_i := U(0,1)
      \]
   b) check for ...
      = new personal best
      = new global best

UNTIL halting criterion met

Another Population Based Approach

Implementing PSO (cont’d)
- continuous search space
  - calibrating
    - population size
    - weights \( c_1, c_2 \)
  - extensions
    - mapping functions for constraints or search space
    - decay on speed
    - additional relative positions
**Heuristic Optimization Methods**

**Summary & Conclusions**

- deterministic + non-deterministic elements
  - generation of new candidate solutions
  - acceptance of new candidate solutions
- general purpose

- selection and implementation issues
  - calibration
  - constraint satisfaction
  - hybrid methods
