Succinct Trees

Jaak Vilo

Thanks to S. Srinivasa Rao

2015
Suppose that $Z$ is the information-theoretical optimal number of bits needed to store some data. A representation of this data is called

- *implicit* if it takes $Z + O(1)$ bits of space,
- *succinct* if it takes $Z + o(Z)$ bits of space, and
- *compact* if it takes $O(Z)$ bits of space.

In computer science, a succinct data structure is a data structure which uses an amount of space that is "close" to the information-theoretic lower bound, but (unlike other compressed representations) still allows for efficient query operations. The concept was originally introduced by Jacobson\cite{1} to encode bit vectors, (unlabeled) trees, and planar graphs. Unlike general lossless data compression algorithms, succinct data structures retain the ability to use them in-place, without decompressing them first. A related notion is that of a compressed data structure, in which the size of the data structure depends upon the particular data being represented.
Succinct Representations of Trees

S. Srinivasa Rao

Seoul National University
Outline

- Succinct data structures
  - Introduction
  - Examples

- Tree representations
  - Motivation
  - Heap-like representation
  - Jacobson’s representation
  - Parenthesis representation
  - Partitioning method
  - Comparison and Applications

- Rank and Select on bit vectors
Succinct data structures

- Goal: represent the data in close to optimal space, while supporting the operations efficiently.
  (optimal -- information-theoretic lower bound)

Introduced by [Jacobson, FOCS ’89]

- An “extension” of data compression.
  (Data compression:
  - Achieve close to optimal space
  - Queries need not be supported efficiently )
Potential applications where memory is limited: small memory devices like PDAs, mobile phones etc.

massive amounts of data: DNA sequences, geographical/astronomical data, search engines etc.
Examples

- Trees, Graphs
- Bit vectors, Sets
- Dynamic arrays
- Text indexes
  - suffix trees/suffix arrays etc.
- Permutations, Functions
- XML documents, File systems (labeled, multi-labeled trees)
- DAGs and BDDs
- ...

Example: Text Indexing

- A text string $T$ of length $n$ over an alphabet $\Sigma$ can be represented using
  - $n \log |\Sigma| + o(n \log |\Sigma|)$ bits,
  (or the even the $k$-th order entropy of $T$)

  to support the following pattern matching queries
  (given a pattern $P$ of length $m$):
  - count the # occurrences of $P$ in $T$,
  - report all the occurrences of $P$ in $T$,
  - output a substring of $T$ of given length
  in almost optimal time.
Example: Compressed Suffix Trees

- Given a text string $T$ of length $n$ over an alphabet $\Sigma$, one store it using $O(n \log |\Sigma|)$ bits, to support all the operations supported by a standard suffix tree such as pattern matching queries, suffix links, string depths, lowest common ancestors etc. with slight slowdown.

- Note that standard suffix trees use $O(n \log n)$ bits.
Example: Permutations

A permutation $\pi$ of $1,\ldots,n$

A simple representation:
- $n \lg n$ bits
- $\pi(i)$ in $O(1)$ time
- $\pi^{-1}(i)$ in $O(n)$ time

Succinct representation:
- $(1+\varepsilon) n \lg n$ bits
- $\pi(i)$ in $O(1)$ time
- $\pi^{-1}(i)$ in $O(1/\varepsilon)$ time (``optimal' trade-off)
- $\pi^k(i)$ in $O(1/\varepsilon)$ time (for any positive or negative integer $k$
- $\lg (n!) + o(n)$ ($< n \lg n$) bits (optimal space)
- $\pi^k(i)$ in $O(\lg n / \lg \lg n)$ time

$\pi$: $\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\pi: & 6 & 5 & 2 & 8 & 1 & 3 & 4 & 7 \\
\pi(1)=6 & \pi^{-1}(1)=5 \\
\pi^2(1)=3 & \pi^{-2}(1)=5 \\
\end{array}$
Memory model

- Word RAM model with word size $\Theta(\log n)$ supporting
  - read/write
  - addition, subtraction, multiplication, division
  - left/right shifts
  - AND, OR, XOR, NOT

operations on words in constant time.

($n$ is the “problem size”)
Succinct Tree Representations
Motivation

Trees are used to represent:

- **Directories** (Unix, all the rest)
- **Search trees** (B-trees, binary search trees, digital trees or *tries*)
- **Graph structures** (we do a tree based search)
- **Search indexes for text** (including DNA)
  - Suffix trees
- **XML documents**
- ...
Drawbacks of standard representations

- Standard representations of trees support very few operations. To support other useful queries, they require a large amount of extra space.

- In various applications, one would like to support operations like “subtree size” of a node, “least common ancestor” of two nodes, “height”, “depth” of a node, “ancestor” of a node at a given level etc.
Drawbacks of standard representations

- The space used by the tree structure could be the dominating factor in some applications.

  - Eg. More than half of the space used by a standard suffix tree representation is used to store the tree structure.

  - “A pointer-based implementation of a suffix tree requires more than $20n$ bytes. A more sophisticated solution uses at least $12n$ bytes in the worst case, and about $8n$ bytes in the average. For example, a suffix tree built upon 700Mb of DNA sequences may take 40Gb of space.”

    -- Handbook of Computational Molecular Biology, 2006
**Standard representation**

Binary tree: each node has two pointers to its left and right children

An $n$-node tree takes $2n$ pointers or $2n \lg n$ bits (can be easily reduced to $n \lg n + O(n)$ bits).

Supports finding left child or right child of a node (in constant time).

For each extra operation (eg. parent, subtree size) we have to pay, roughly, an additional $n \lg n$ bits.
Can we improve the space bound?

- There are less than $2^{2n}$ distinct binary trees on $n$ nodes.
  - "The Art of Computer Programming", Volume 4, Fascicle 4: *Generating all trees*

- $2n$ bits are enough to distinguish between any two different binary trees.

- Can we represent an $n$ node binary tree using $2n$ bits?
How Many Binary Trees Are There?

There are five distinct shapes of binary trees with three nodes:

![Binary Tree Diagram](http://cs.lmu.edu/~ray/notes/binarytrees/)

But how many are there for n nodes?

Let $C(n)$ be the number of distinct binary trees with $n$ nodes. This is equal to the number of trees that have a root, a left subtree with $j$ nodes, and a right subtree of $(n-1)-j$ nodes, for each $j$. That is,

$$C(n) = C(0)C(n-1) + C(1)C(n-2) + \ldots + C(n-1)C(0)$$

which is

$$C_0 = 1 \quad \text{and} \quad C_n = \sum_{i=0}^{n-1} C_iC_{n-1-i} \quad \text{for } n \geq 1.$$
The first few terms:

\[\begin{align*}
  c(0) &= 1 \\
  c(1) &= c(0)c(0) = 1 \\
  c(2) &= c(0)c(1) + c(1)c(0) = 2 \\
  c(3) &= c(0)c(2) + c(1)c(1) + c(2)c(0) = 5 \\
  c(4) &= c(0)c(3) + c(1)c(2) + c(2)c(1) + c(3)c(0) = 14
\end{align*}\]

You can prove

\[C_n = \frac{1}{n+1} \binom{2n}{n} \quad \text{for } n \geq 0.\]

Here's the number of 8-node binary trees:

\[\begin{align*}
  C(8) &= \frac{1}{9} \times \frac{1}{8!} \times 16 \times 15 \times 14 \times 13 \times 12 \times 11 \times 10 \\
       &= \frac{16 \times 15 \times 14 \times 13 \times 12 \times 11 \times 10}{9 \times 8! \times 8!} \\
       &= \frac{13 \times 11 \times 10}{8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1} = 1430
\end{align*}\]

Also see Wikipedia's article on the Catalan Numbers.
Heap-like notation for a binary tree

Add external nodes

Label internal nodes with a 1 and external nodes with a 0

Write the labels in level order

1 1 1 1 0 1 1 0 1 0 0 1 0 0 0 0 0 0

One can reconstruct the tree from this sequence

An \( n \) node binary tree can be represented in \( 2n+1 \) bits.

What about the operations?
Heap-like notation for a binary tree

left child(x) = \[2x\]
right child(x) = \[2x+1\]
parent(x) = \[[x/2]\]

\(x \rightarrow x\): # 1's up to \(x\)
\(x \rightarrow x\): position of \(x\)-th 1
Heap-like notation for a binary tree

```
1 1 1 1 0 1 1 0 1 0 0 1 0 0 0 0 0
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17
```

COLOR
Example 2 (JV)
Example 2 (JV)

Node= 1 2 3 4 5 6
BitVector= 1 0 1 0 1 0 1 1 1 0 0 0 0
Bvrank= 1 2 3 4 5 6 7 8 9 10 11 12 13

Rchild(4) = Rank 1 (2*4 + 1) = 6
Example 2 (JV)

Node= 1 2 3 4 5 6
BitVector= 1 0 1 0 1 0 1 1 1 0 0 0 0
Bvrank= 1 2 3 4 5 6 7 8 9 10 11 12 13

Parent(5) =

=> 8 => 4th node

4th node is at index 7
Rank/Select on a bit vector

Given a bit vector $B$

$\text{rank}_1(i) = \# 1$’s up to position $i$ in $B$

$\text{select}_1(i) = \text{position of the } i\text{-th } 1 \text{ in } B$

(similarly $\text{rank}_0$ and $\text{select}_0$)

$$
\begin{array}{cccccccccccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 \\
\hline
B: & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
$$

Given a bit vector of length $n$, by storing an additional $o(n)$-bit structure, we can support all four operations in $O(1)$ time.

$$
\begin{array}{l}
\text{rank}_1(5) = 3 \\
\text{select}_1(4) = 9 \\
\text{rank}_0(5) = 2 \\
\text{select}_0(4) = 7 \\
\end{array}
$$

An important substructure in most succinct data structures.

Implementations: [Kim et al.], [Gonzalez et al.], ...
Binary tree representation

- A binary tree on $n$ nodes can be represented using $2n + o(n)$ bits to support:
  - parent
  - left child
  - right child

in constant time.

[Jacobson '89]
Supporting Rank

- Store the rank up to the beginning of each block: \((m/b) \log m\) bits
- Store the `rank within the block’ up to the beginning of each sub-block: \((m/b)(b/s) \log b\) bits
- Store a pre-computed table to find the rank within each sub-block: \(2^s s \log s\) bits
Rank/Select on bit vector

- Choosing $b = (\log m)^2$, and $s = (1/2)\log n$ makes the overall space to be $O(m \log\log m / \log m) (= o(m))$ bits.

- Supports rank in constant time.

- Select can also be supported in constant time using an auxiliary structure of size $O(m \log\log m / \log m)$ bits.

[Clark-Munro `96] [Raman et al. `01]

http://alexbowe.com/rrr/ -> RRR succinct rank/select index...
Lower bounds for rank and select

- If the bit vector is read-only, any index (auxiliary structure) that supports rank or select in constant time (in fact in $O(\log m)$ bit probes) has size $\Omega(m \log \log m / \log m)$.

[Miltersen ‘05] [Golynski ‘06]
Space measures

- Bit-vector (BV):
  - space used be $m + o(m)$ bits.

- Bit-vector index:
  - bit-sequence stored in read-only memory
  - index of $o(m)$ bits to assist operations

- Compressed bit-vector: with n 1’s
  - space used should be $B(m,n) + o(m)$ bits.

$$B(m,n) = \left\lceil \log\left( \binom{m}{n} \right) \right\rceil$$

(Entry in Encyclopaedia of Algorithms)
Ordered trees?

A rooted ordered tree (on n nodes):

Navigational operations:
- parent(x) = a
- first child(x) = b
- next sibling(x) = c

Other useful operations:
- degree(x) = 2
- subtree size(x) = 4
Ordered trees

- A binary tree representation taking $2n+o(n)$ bits that supports parent, left child and right child operations in constant time.

- There is a one-to-one correspondence between binary trees (on $n$ nodes) and rooted ordered trees (on $n+1$ nodes).

- Gives an ordered tree representation taking $2n+o(n)$ bits that supports first child, next sibling (but not parent) operations in constant time.

- **We will now consider ordered tree representations that support more operations.**
Level-order degree sequence

Write the degree sequence in level order

3 2 0 3 0 1 0 2 0 0 0 0

But, this still requires $n \lg n$ bits

Solution: write them in unary

1 1 1 0 1 1 0 0 1 1 1 0 0 1 0 0 1 1 0 0 0 0 0

Takes $2n-1$ bits

A tree is uniquely determined by its degree sequence
Supporting operations

Add a dummy root so that each node has a corresponding parent

$1\ 0\ 1\ 1\ 1\ 0\ 1\ 1\ 0\ 0\ 1\ 1\ 1\ 0\ 0\ 1\ 0\ 0\ 1\ 1\ 0\ 0\ 0\ 0\ 0$

$1\ 2\ 3\ 4\ 5\ 6\ 7\ 8\ 9\ 10\ 11\ 12$

Node $k$ corresponds to the $k$-th 1 in the bit sequence

$\text{parent}(k) = \#\ 0$'s up to the $k$-th 1

Children of $k$ are stored after the $k$-th 0

Supports: parent, i-th child, degree

(Using rank and select)
Level-order unary degree sequence

- Space: $2n + o(n)$ bits

- Supports
  - parent
  - i-th child (and hence first child)
  - next sibling
  - degree
    in constant time.

Does not support subtree size operation.

[Jacobsen ‘89]
[Implementation: Delpratt-Rahman-Raman ‘06]
Another approach

Write the degree sequence in depth-first order

3  2  0  1  0  0  3  0  2  0  0  0

In unary:

1 1 1 0 1 1 0 0 1 0 0 0 1 1 1 0 0 1 1 0 0 0 0

Takes $2n-1$ bits.

The representation of a subtree is together.

Supports subtree size along with other operations. (Apart from rank/select, we need some additional operations.) Which?
Depth-first unary degree sequence (DFUDS)

- Space: $2n+o(n)$ bits

- Supports
  - parent
  - i-th child (and hence first child)
  - next sibling
  - degree
  - subtree size
    - in constant time.

[Benoit et al. ’05] [Jansson et al. ‘07]
Other useful operations

XML based applications:

level ancestor(x,l): returns the ancestor of x at level l

eg. level ancestor(11,2) = 4

Suffix tree based applications:

LCA(x,y): returns the least common ancestor of x and y

eg. LCA(7,12) = 4
Parenthesis representation

Associate an open-close parenthesis-pair with each node.

Visit the nodes in pre-order, writing the parentheses.

length: $2n$

space: $2n$ bits

One can reconstruct the tree from this sequence:

( ( ( ) ( ( ) ) ) ) ( ) ( ( ) ( ( ) ( ) ) ( ) ) )
Operations

**parent** – enclosing parenthesis

**first child** – next parenthesis (if ‘open’)

**next sibling** – open parenthesis following the matching closing parenthesis (if exists)

**subtree size** – half the number of parentheses between the pair

With $o(n)$ extra bits, all these can be supported in constant time
Parenthesis representation

- Space: \(2n + o(n)\) bits

- Supports:
  - parent
  - first child
  - next sibling
  - subtree size
  - degree
  - depth
  - height
  - level ancestor
  - LCA
  - leftmost/rightmost leaf
  - number of leaves in the subtree
  - next node in the level
  - pre/post order number
  - i-th child

  in constant time.

[Munro-Raman ‘97] [Munro et al. 01] [Sadakane ‘03] [Lu-Yeh ‘08]
[Implementation: Geary et al., CPM-04]
A different approach

- If we group $k$ nodes into a block, then pointers with the block can be stored using only $\lg k$ bits.

- For example, if we can partition the tree into $n/k$ blocks, each of size $k$, then we can store it using $(n/k) \lg n + (n/k) k \lg k = (n/k) \lg n + n \lg k$ bits.

A careful two-level `tree covering’ method achieves a space bound of $2n+o(n)$ bits.
Tree covering method

- Space: $2n+o(n)$ bits

- Supports:
  - parent
  - first child
  - next sibling
  - subtree size
  - degree
  - depth
  - height
  - level ancestor
  - LCA
  - leftmost/rightmost leaf
  - number of leaves in the subtree
  - next node in the level
  - pre/post order number
  - i-th child

in constant time.

[Geary et al. ‘04] [He et al. ‘07] [Farzan-Munro ‘08]

</table>
Unified representation

- A single representation that can emulate all other representations.

- Result: A $2n + o(n)$ bit representation that can generate an arbitrary word ($O(\log n)$ bits) of DFUDS, PAREN, or PARTITION in constant time.

- Supports the union of all the operations supported by each of these three representations.

[Farzan et al. ‘09]
Applications

- Representing
  - suffix trees
  - XML documents (supporting XPath queries)
  - file systems (searching and Path queries)
  - representing BDDs
  - ...
Open problems

- Making the structures dynamic (there are some existing results)

- Labeled trees (two different approaches supporting different sets of operations)

- Other memory models
  - External memory model (a few recent results)
  - Flash memory model
  - (So far mostly RAM model)
I/O Model [AV88]

Parameters

- **N**: Elements in structure
- **B**: Elements per block
- **M**: Elements in main memory
