Regular expression

• **Definition:** A *regular expression* RE is a string on the set of symbols $\Sigma \cup \{ \varepsilon, |, \cdot, *, (, ) \}$, which is recursively defined as follows. RE is
  
  – an empty character $\varepsilon$,
  – a character $\alpha \in \Sigma$,
  – $(\text{RE}_1)$,
  – $(\text{RE}_1 \cdot \text{RE}_2)$,
  – $(\text{RE}_1 | \text{RE}_2)$, and
  – $(\text{RE}_1^*)$,

  where $\text{RE}_1$ and $\text{RE}_2$ are regular expressions.
Example

\[
(((A \cdot T) \mid (G \cdot A)) \cdot (((A \cdot G) \mid ((A \cdot A) \cdot A))^*)
\]

- we can simplify

\[
(AT \mid GA)((AG \mid AAA)^*)
\]

- Often also this is used:

\[
RE^+ = RE \cdot RE^*
\]
Why?

• Regular expression defines a language

• A set of words from $\Sigma^*$

• A convenient short-hand

• $(AT|GA)((AG|AAA)^*) \Rightarrow AT, \ ATAG, \ GAAAA, \ GAAGAAAAAA, \ ...$

• Infinite set
**Language represented by RE**

**Definition:** A *language represented by a regular expression* $RE$ is a set of strings over $\Sigma$, which is defined recursively on the structure of $RE$ as follows:

- if $RE$ is $\varepsilon$, then $L(RE) = \{\varepsilon\}$, the empty string
- if $RE$ is $\alpha \in \Sigma$, then $L(RE) = \{\alpha\}$, a single string of one character
- if $RE$ is of the form $(RE_1)$, then $L(RE) = L(RE_1)$
- if $RE$ is of the form $(RE_1 \cdot RE_2)$, then $L(RE) = L(RE_1) \cdot L(RE_2)$, where $w = w_1 w_2$ is in $L(RE)$ if $w_1 \in L(RE_1)$ and $w_2 \in L(RE_2)$. (We call $\cdot$ the concatenation operator)
- if $RE$ is of the form $(RE_1 | RE_2)$, then $L(RE) = L(RE_1) L(RE_2)$, the union of two languages. (We call $|$ the union operator)
- if $RE$ is of the form $(RE_1 *)$, then $L(RE) = L(RE)^* = \bigcup_{i \geq 0} L(RE_1)^i$, where $L^0 = \{\varepsilon\}$ and $L^i = L \cdot L^{i-1}$. (We call $*$ the star operator)

• \( L( (AT|GA)((AG|AAA)^*) ) = \{ \text{AT, GA, ATAG, GAAG, ATAAA, GAAAA, ATAGAG, ATAGAAA, ATAAAG, ...} \} \)

• \( \Sigma^* \) denotes all strings over alphabet \( \Sigma \)
• The \textit{size} of a regular expression \( RE \) is the number of characters of \( \Sigma \) in it.
• Many complexities are based on this measure.
A different example definition

- Just as finite automata are used to recognize patterns of strings, regular expressions are used to generate patterns of strings. A regular expression is an algebraic formula whose value is a pattern consisting of a set of strings, called the language of the expression.
- Operands in a regular expression can be:
  - characters from the alphabet over which the regular expression is defined.
  - variables whose values are any pattern defined by a regular expression.
  - epsilon which denotes the empty string containing no characters.
  - null which denotes the empty set of strings.
- Operators used in regular expressions include:
  - * Concatenation: If R1 and R2 are regular expressions, then R1R2 (also written as R1.R2) is also a regular expression.
    \[ L(R1R2) = L(R1) \text{ concatenated with } L(R2) \]
  - * Union: If R1 and R2 are regular expressions, then R1 | R2 (also written as R1 U R2 or R1 + R2) is also a regular expression.
    \[ L(R1|R2) = L(R1) \text{ U } L(R2) \]
  - * Kleene closure: If R1 is a regular expression, then R1* (the Kleene closure of R1) is also a regular expression.
    \[ L(R1^*) = \text{epsilon U } L(R1) \text{ U } L(R1R1) \text{ U } L(R1R1R1) \text{ U } ... \]
- Closure has the highest precedence, followed by concatenation, followed by union.
Regexp Matching

• The problem of searching regular expression RE in a text T is to find all the factors of T that belong to the language L(RE).
  • Parsing
  • Thompsons NFA construction (1968)
    Glushkov NFA construction (1961)
  • Search with the NFA
  • Determinization
  • Search with the DFA
  • Or, search by extracting set of strings, multi-pattern matching, and verification of real occurrences.
Matching of RE-s

Regular expression → Parse → NFA → DFA → Occurrences
Parse tree

**Deterministic finite automaton DFA**

**Definition** DFA is a quintuple $M=(Q, \Sigma, \delta, q_0, F)$, where
- $Q$ is the finite set of states of an automaton
- $\Sigma$ is the input alphabet
- $\delta : Q \times \Sigma \rightarrow Q$ is the transition function
- $q_0 \in Q$ is the initial state
- $F \subseteq Q$ is a set of accepting final states

**Usage:**
- Transition step - $(q, aw) \rightarrow (q', w)$ if $\delta(q,a) = q'$, $w \in \Sigma^*$
- Accepted language: $L(M) = \{ w \mid (q_0, w) \rightarrow^* (q, \varepsilon), q \in F \}$
Non-deterministic finite automaton NFA

**Definition** NFA is a quintuple $M=(Q, \Sigma, \delta, q_0, F)$, where

- $Q$ is the finite set of states of an automaton
- $\Sigma$ is the input alphabet
- $\delta : Q \times \Sigma \rightarrow P(Q)$ is the transition function (a set)
- $q_0 \in Q$ is the initial state
- $F \subseteq Q$ is a set of accepting final states

**Usage:**

- Transition step - $(q, aw) |\rightarrow (q', w)$ if $q' \in \delta(q,a)$, $a \in \Sigma \cup \{\varepsilon\}$, $w \in \Sigma^*$
- Accepted language: $L(M) = \{ w \mid (q_0, w) \mid\rightarrow^* (q, \varepsilon), q \in F \}$
Q = \{S_0, S_1, S_2\}
\Sigma = \{a, b\}

Regexp -> NFA / DFA

• Construction of an automaton from the regular expression
• Regular expressions are mathematical and human-readable descriptions of the language
• Automata represent computational mechanisms to evaluate the language
• One needs to be able to parse the regular expression and to construct an automaton for matching it.
See **Navarro and Raffinot** Flexible Pattern Matching in Strings. (Cambridge University Press, 2002). pp. 103.

- Automaadi konstruktsioon: [Regulaarest avaldisест mittedetermineeritud automaadi moodustamine](https://example.com) (Meelis Roos) (kohalik)

- Tsitaat:

  Nii saadud lõplik automaat pole determineeritud, kuna me kasutame juba primitiivsetes automaatides mittedetermineeritust. Lõpliku automaadi võib hiljem muidugi eraldi determineerida.
Thompson construction

• Primitive automata

• Composition

• No optimality, no compression, etc.
Thompson construction: 2 primitive automata

• Symbol $\epsilon$:

• Terminal symbol $a$:
Union and Concatenation

- \( s \mid t \)
  - \( \epsilon \)
  - \( N(s) \) to \( i \) to \( \epsilon \) to \( f \) to \( \epsilon \) to \( N(t) \) to \( f \)

- \( st \)
  - \( i \) to \( N(s) \) to \( f \) to \( N(t) \) to \( f \)
Closure

• $s^*$
Example

- $a^*(ba|c)$
Fig. 5.5. Thompson automaton construction for the regular expression (AA|AT)((AG|AAA)*).
• Produces up to 2m states, but it has interesting properties, such as ensuring a linear number of edges, constant indegree and outdegree, etc.
Simulation of an NFA

Input: NFA $M_A = (Q, \Sigma, \delta, q_0, F)$, Text $S = s[1..n]$

Output: States after each character read $Q_0, Q_1, \ldots, Q_n$

NB: $S \in L(M_A)$ only if $F \subseteq Q_n$.

Initially queue and sets $Q_i$ are empty

1. for $i = 0$ to $n$ do // for each symbol of text
2. mark all $q \in Q$ unreached
3. if ($i == 0$) // Initialise start state
4. then
5. $Q_0 = q_0$; queue = q0; mark q0 as reached
6. else
7. foreach $q \in Q_{i-1}$ // Main transitions on $s[i]$
8. foreach $p \in \delta(q, s[i])$ // All transitions on $s[i]$
9. if $p$ not yet reached
10. $Q_i = Q_i \cup p$
11. push( queue, p )
12. mark p as reached
13. while queue $\neq \emptyset$
14. $q = \text{take( queue )}$ // Follow up on all $\epsilon$ - transitions
15. foreach $p \in \delta(q, \epsilon)$ // All $\epsilon$ - transitions
16. if $p$ not yet reached
17. $Q_i = Q_i \cup p$
18. push( queue, p )
19. mark p as reached
• **Theorem** Time complexity of the NFA simulation is $O(||M_A|| \cdot n)$ where $||M_A||$ is the total number of states and transitions of $M_A$, $||M_A|| \leq 6 |A|$.

• **Proof** - During one step all states are manipulated only once, since all states are marked reached. There is at most $n$ steps. The size of the automaton is at most $6 |A|$ where $|A|$ is the length of the regular expression.
Glushkov construction

\[(A_1 \quad T_2 \quad | \quad G_3 \quad A_4) \quad ((A_3 \quad G_6 \quad | \quad A_7 \quad A_8 \quad A_9)^*) \]

Fig. 5.6. Marked Glushkov automaton built on the marked regular expression \((A_1 \quad T_2 | G_3 A_4)((A_5 G_6 | A_7 A_8 A_9)^*)\). The state 0 is initial. Double-circled states are final.

To obtain the Glushkov automaton of the original \(RE\), we simply erase the position indices in the marked automaton. At this step, the automaton usually becomes nondeterministic. The new automaton recognizes the language \(L(RE)\). The Glushkov automaton of our example \((AT | GA) ((AG) \quad AAA)^*\) is shown in Figure 5.7.

Fig. 5.7. Glushkov automaton built on the regular expression \((AT | GA) ((AG) \quad AAA)^*\). The state 0 is initial. Double-circled states are final. The automaton is derived from the marked automaton by simply erasing the position indices.
Fig. 5.6. Marked Glushkov automaton built on the marked regular expression \((A_1 T_2|G_3 A_4)((A_5 G_6|A_7 A_8 A_9)*). The state 0 is initial. Double-circled states are final.

To obtain the Glushkov automaton of the original \(RE\), we simply erase the position indices in the marked automaton. At this step, the automaton usually becomes nondeterministic. The new automaton recognizes the language \(L(RE)\). The Glushkov automaton of our example \((AT|GA)((AG|AAA)*)\) is shown in Figure 5.7.

Fig. 5.7. Glushkov automaton built on the regular expression \((AT|GA)((AG|AAA)*)\). The state 0 is initial. Double-circled states are final. The automaton is derived from the marked automaton by simply erasing the position indices.
Fig. 5.19. Glushkov automaton built on the regular expression \(((GA|AAA)^*)\)

\((TA|AG)\).
• No $\varepsilon$ links
• All incoming arcs have the same character label
• To reach a certain state always the same character from text had to be read.
• Construction: worst case is $O(m^3)$ since poor performance for star closures...
• But this has been speeded up a bit
Matching of RE-s

- Regular expression
- Parse
- NFA
- DFA
- Occurrences
NFA -> DFA

• Why?

• More straightforward (i.e. faster) to match/simulate
Determinization of a NFA into a DFA

• Maintain at each stage a set of states reachable from previous set on the given character. (Remove ε transitions.)

• Represent every reachable combination of states of a NFA as a new state of DFA

• From each state there has to be only one transition on a given character.

• Automata for Matching Patterns Handbook of Formal Languages (kohalik)

• Navarro and Raffinot Flexible Pattern Matching in Strings. (Cambridge University Press, 2002). pp. 106 -> pp 115
Maintain at each stage a set of states reachable from previous set on the given character. (Remove ε transitions.)

Represent every reachable combination of states of a NFA as a new state of DFA

From each state there can be only one transition on a given character.

5.3 Classical approaches to regular expression searching

From Thompson’s NFA
5.3 Classical approaches to regular expression searching

From Thompson’s NFA

From Glushkov’s NFA

Fig. 5.12. The DFAs resulting from Thompson’s and Glushkov’s NFAs.
Minimization of automata

• DFA construction does not always produce the minimal automaton

• Smaller -> better(?)

• Must still represent equivalent languages!
Minimization of automata

- Language is simply a subset of all possible strings of $\Sigma^*$
- Regular language is the language that can be described using regular expressions and recognized by a finite automaton (no pushdown, multi-tape, or Turing machines)
- Two automatons that recognize exactly the same language are equivalent
- The automaton that has fewest possible states from the same equivalence class, is the minimal
- Automaton with more states is called redundant
- The automaton construction techniques do not create the minimal automaton
- It would be easier to understand nonredundant automaton
- Smaller automaton consumes less memory
- The manipulation is faster
Minimization

• A compiler course subject
• Minimization description (L4_RegExp/min-fa.html)
  A: Merge all equivalent states until minimum achieved
  B: Start from minimal possible (2-state) and split states until no conflicts
• Fact. Equivalent states go to equivalent states under all inputs.
• Recognizer for \((aa \mid b)^*ab(bb)^*\)
Step 1: Generate 2 equivalence classes: final and other states

<table>

<td>3:D</td>
<td>7:A</td>
<td>E</td>
</tr>
</tbody>
</table>

All states are consistent
(aa | b)*ab(bb)*
$(aa \mid b)^*ab(bb)^*$
Construct a DFA from the regular expression

• Usually NFA is constructed, and then determinized
• McNaughton and Yamada proposed a method for direct construction of a DFA
\[(a | b)^* \text{aba}\# \rightarrow \text{DFA}\]
• Example: Let's analyze RE = (a ∪ b)*aba
• Add end symbol #: (a ∪ b)*aba#
• Make a parse tree
  – Leaves represent symbols of Σ from RE
  – Internal nodes - operators
• Give a unique numbering of leaves
• Position nr is **active** if this can **represent the next symbol**
• DFA states and transitions are made from the tree:
  • A state of DFA corresponds to a set of positions that are active after reading some prefix of the input
  • Initial state is (1, 2, 3) (when nothing has been read yet)
  • DFA contains transitions q →ₘ a q', where q' are position nrs that are activated when in positions of q the character a is read.
• Final states are those containing the position number of #
(a | b)* aba# to DFA

Construction of regular expressions from the automata

• It is possible to start from an automaton and then generate the regular expression that describes the language recognized by the automaton.

• The program JFLAP for transforming FSA to regular expressions can be downloaded from http://www.jflap.org/, or http://www.cs.duke.edu/~rodger/tools/jflap/indexold.html

• In the bottom of page there are links to "current version".

\[(aa \mid b) (ba)^* (bb \mid a)\]
Moodusta reg. avaldis sellest automaadist

\[ ab \mid (aa \mid b)(ba)^* (bb \mid a) \]
Moodusta reg. avaldis sellega automaadist

( ab | (aa | b)(ba)* (bb | a ) )*
Filtering approaches for regular expression searches

• Identify a (sub)set of prefixes or factors that are necessarily present in the language represented by regexp.

• Use multi-pattern matching techniques for matching them all simultaneously

• In case of a match use the automaton to verify the occurrence
• Prefixes
• Imin - the shortest occurrence length (to avoid missing short occurrences)
• ((GA|AAA)*(TA|AG)) the set of 2-long prefixes is \{ GA, AA, TA, AG \}
• (AT|GA)(AG|AAA)((AG|AAA)+) Imin=6
• \{ ATAGAG, ATAGAA, ATAAAA, GAAGAG, GAAGAA, GAAAAA \}
Fig. 5.24. Automaton to recognize all the reverse prefixes of the regular expression \(((GA|AAA)^*)(TA|AG)\).
• (AG|GA)ATA((TT)*)
• The string ATA is a necessary factor.
• Gnu grep uses such heuristics
• Can be developed to utilise a lot of knowledge about possible frequencies of occurrences, speed of multi-pattern matchers etc.
Summary

- Regular expression
- Parse
- NFA
- DFA
- Occurrences
- minimize
Learning languages

Grammatical inference

Q: What is the language represented by the positive examples?

A1: List of positive examples

A2: Minimal automaton that recognises + examples, and none of the – examples?

Finding A2 in general a computationally hard problem
Graph algorithms?

• Shortest path from start to end?

• Minimal cost path? (what would be the weights?)
